ABSTRACT: Pneumatosis intestinalis (PI) also called as pneumatosis coli/ pneumatosis cystoides intestinalis) is the presence of multiple gas/ air filled cysts in the bowel wall. The pathogenesis is poorly understood and is probably multifactorial. The presentation may be either an incidental diagnosis or may be associated with various gastrointestinal diseases. We report a case of 76- year- old male presented with intestinal obstruction symptoms, diagnosed to be small bowel PI associated with lymphangiectasia. In this report we emphasize the pathogenesis of PI due to lymphatic disruption.

KEYWORDS: Pneumatosis Cystoides Intestinalis, lymphangiectasia, Crohn's disease

INTRODUCTION:

Pneumatosis intestinalis (PI) is a rare condition characterized by the presence of multiple gas (air) filled cysts in the bowel wall¹. The presenting features of this condition are nausea, vomiting, abdominal pain and abdominal distension. It may be asymptomatic with an incidental radiological diagnosis. Multiple theories have been hypothesized for the pathogenesis of PI and the proven theories are bacterial, mechanical and mucosal disruption theories. PI caused by lymphatic channels disruption is not clearly understood, the etiology being increased intraluminal pressure causing leakage of gas/ air and lymph contents from the dilated lymphatics in to the bowel wall. It is otherwise known as lymphopneumatosis cystoids intestinalis or cystic lymphopneumatosis².

There are very few reports of PI based on lymphatic disruption pathogenesis. We present a rare case of small bowel PI associated with lymphangiectasia .

CASE REPORT:

A 72 year- old male presented with complaints of abdominal distension, vomiting and abdominal pain for two weeks. No history of GI bleeding, fever, jaundice or altered bowel and bladder movements were present. He underwent hemicolectomy with small bowel resection and anastomosis for terminal ileal stricture couple of months ago. Post- operatively patient had supraventricular tachycardia and was treated with beta blockers and aspirin.

On examination: patient was conscious, oriented, and a febrile. No signs of pallor, icterus, enlarged nodes and pedal edema. Abdomen examination revealed abdominal distension, visible gastric peristalsis and right iliac fossa tenderness. Cardio vascular, respiratory and neurological examinations were normal. Renal function test showed hypokalemia. Liver function test showed marked hypoalbuminemia.

CT –enterography was done showed features of PI and air under the diaphragm. Exploratory laparotomy was done and intraoperative findings were dilated small bowel loops with adhesions. Grossly, the specimen showed multiple tiny pale brown cysts ranging in size from 0.2cm to 2.5cms over the entire length of the intestine with intervening normal serosal surface. Microscopy, showed preserved mucosal architecture and multiple cystic spaces of varying sizes in the submucosal and subserosal layers. Few spaces were lined by flattened and multinucleated giant cells. However the lining was absent in some of the spaces. The stroma was fibrous and showed scattered lymphoplasmacytic infiltrates, dilated lymphatic channels and congested blood vessels. Previous biopsy report from the stricture part of hemicolectomy specimen was small bowel lymphangiectasia with no obvious evidence of Crohn's disease (CD) such as crypt architecture distortion, submucosal granulomas and cryptitis or ischemic etiology.

Fig 1: CT scan showing small bowel pneumatosis and gross appearance of the small bowel pneumatosis intestinalis (PI). Inset showing submucosal PI, (indicated by arrow).

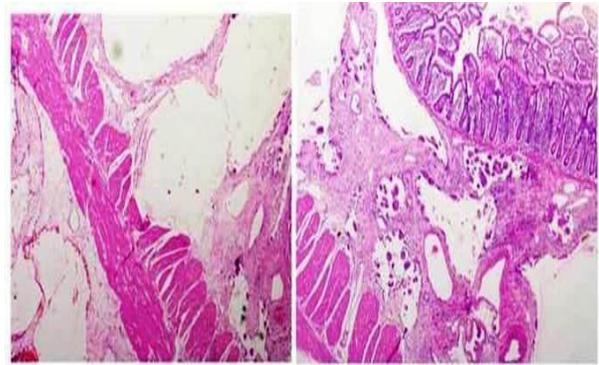

Fig 2: Microscopic sections showing small bowel submucosal and subserosal cystic spaces lined by multinucleated giant cells (G). (H&E x 10)

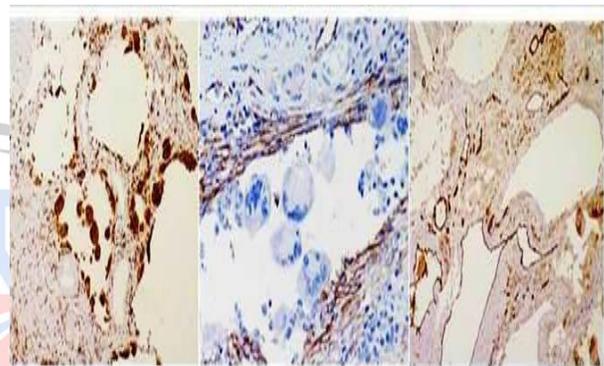

Fig 3: Immunostain expression of CD 68, D2-40 and CD 31 on the multinucleated giant cells, Podoplanin (D2-40) immunostain expression on the pericycystic interstitium and lymphatic channels respectively.

IHC study, showed a strong linear expression (nuclear positivity) of Podoplanin (D2-40) in the pericycystic interstitium and the lymphatic endothelial cells. CD68 was expressed (cytoplasmic positivity) in flattened cells and multinucleated giant cells. CD 31 immunopositivity (nuclear positivity) was observed in lymphatic and vascular endothelial cells and negative in cystic spaces.

In the immediate post-operative period patient had persistent hypotension and shock, In spite of good supportive care he died of cardiopulmonary arrest.

DISCUSSION:

PI is a rare entity accounting about 0.03 to 0.37 % incidences in general population and the etiology is multifactorial. It includes primary/ sporadic (15%) or fulminant (85%) causes such as ischemia, infections, post-surgical or inflammatory conditions (Crohn's/ ulcerative colitis)¹. Few of these predisposing factors were noted in our case such as history of previous surgery and the coexistence of CD features.

There are very few reports of PI due to predisposing CD⁵⁻⁷. The pathogenic mechanism explained was inflammation induced mucosal injury and/or increased intraluminal pressure allowing intraluminal gas to enter the damaged bowel wall⁸. This case didn't show obvious mucosal injury favoring CD causing PI.

The other possible pathogenesis was explained by Pedicaet al⁹ in their study, that there is an increased lymphangiogenesis and diffuses lymphangiectasia in CD patients when compared to their normal controls. Our patient exhibited lymphangiectasia as the prominent finding.

Harries et al¹⁰ stated that the congenital lymphatic abnormality directly plays a role in the development of PI. They also described about the spatial relationship of abnormal small bowel lymphatics and PI formation.

In the study done by Staudacher and Bencini³ in the intestine of hogs clearly demonstrates the distended lymphatics forming the cystic spaces of PI. Haboubiet al⁴ demonstrated the lymphatic vessel forming cystic spaces of PI by light and electron microscopy. Gui et al² in another study observed the expression of lymphatic marker [podoplanin(D2-40)] in the pericyclic interstitium of all cases studied, suggesting that PI is due to the rupture of the distended lymphatics. This finding is concomitant in our study thereby supporting the lymphatic theory of PI.

CONCLUSION:

This case is unique in presentation, as the primary diagnosis itself posed a challenge. So far there has been no case reports of PI associated with lymphangiectasia. Combined clinical and radiological investigations with a high index of

suspicion leads to earlier diagnosis and management of this condition otherwise a rare entity.
